**Experimental Section**

**Materials:**

Cholesterol, 1,2-dihexadecanoyl-sn-glycero-3-phosphocholine (DPPC), and 2,2-dimethyl-2-silapentane-5-sulfonate (DSS), and fluorescein isothiocyanate (FITC) were purchased from commercial resources and used without further purification. The amphiphilic \( p \)-sulfonatocalix[4]arenes bearing tetrabutyl and tetrahexyl chains (SC4AH and SC4AB), biotinylated pyridinium (BtPy), FITC-conjugated pyridinium (FITCPy) and bispyridinium salts of methyl viologen (MV and bis-MV) were synthesized according to the reported procedures.\(^1\)\(^-\)\(^5\)

**Preparation of DPPC–SC4AH and DPPC–SC4AB Liposomes.** Vesicular solutions were prepared by using the previously reported film hydration method. In brief, DPPC (7.34 mg) and cholesterol (1.29 mg) were dissolved in 2 mL chloroform. Chloroform was evaporated using a rotary evaporator to create a thin lipid film. This film was re-suspended in 2 mL SC4AH (0.25 mM) or SC4AB (0.5 mM) aqueous solution after 0.5 h of stirring at 55 °C and sonicated for another 0.5 h at the same temperature. The resulting suspension was extruded through a 200 nm membrane while hot to create the lipid vesicles. Giant mixed vesicles prepared from a similar procedure but without sonication and extrusion to reduce the diameter.

**Preparation of Guest-Decorated Liposomes.** FITCPy or BtPy were added to vesicular solutions and the resulting solution was gently stirred for 2 h at room temperature to introduce tags to the surface of vesicles.

**Measurements:**
The optical transmittance of the aqueous solution was measured in a quartz cell (light path 10 mm) on a Shimadzu UV-3600 spectrophotometer equipped with a PTC-348WI temperature controller. Steady-state fluorescence spectra were recorded in a conventional quartz cell (light path 10 mm) on a Varian Cary Eclipse equipped with a Varian Cary single-cell Peltier accessory to control the temperature. $^1$H NMR spectra were recorded on a Bruker AV400 spectrometer in D$_2$O at 25 °C. DSS is used as internal reference.

**Isothermal Titration Calorimetry (ITC).** A thermostated and fully computer-operated isothermal calorimetry (VP-ITC) instrument, purchased from Microcal Inc., Northampton, MA, was used for all microcalorimetric experiments. All microcalorimetric titrations were performed in aqueous solution at atmospheric pressure and 25 °C. Each solution was degassed and thermostatted by a ThermoVac accessory before the titration experiment. Twenty-nine successive injections were made for titration experiment. A constant volume (10 $\mu$L/injection) of BtPy solution in a 0.250 mL syringe was injected into the reaction cell (1.4227 mL) charged with SC4AB aqueous solution.

**High-Resolution TEM measurements.** High-resolution TEM images were acquired using a Tecnai 20 high-resolution transmission electron microscope operating at an accelerating voltage of 200 kV. The sample for TEM measurements was prepared by dropping the solution onto a copper grid. The grid was then air-dried.

**DLS measurements.** The samples were examined on a laser light scattering spectrometer (BI-200SM) equipped with a digital correlator (TurboCorr) at 636 nm at
a scattering angle of 90°. The hydrodynamic diameter was determined by dynamic light scattering experiments.

**Zeta potential measurements.** Zeta potential values were determined on a Brookheaven ZetaPALS (Brookheaven Instrument, USA) at 25 °C. The instrument utilizes phase analysis light scattering to provide an average over multiple particles. Doubly distilled water was used as the background electrolyte for zeta potential measurements.

**Confocal laser scanning microscopy.** For the purpose of giant vesicle imaging, a drop of giant mixed vesicular solution (0.5 mM) after incubation with FITCPy (0.005 mM) on a slide glass was observed by a confocal laser scanning microscope (Olympus FV1000) with excitation at 490 nm for FITCPy. For the purpose of biotin receptor-mediated cancer cell targeting, MCF7 cells were firstly cultured in Roswell Park Memorial Institute's medium (RPMI 1640) supplemented with 10% FBS under a humidified air with 5% CO₂ at 37 °C. Then, MCF7 cells were seeded in a 4-well plate in 1.0 mL complete RPMI 1640 medium. After incubating for 24 h, the cells were treated with corresponding sample. After 6 h, the culture media were removed and cells were washed with PBS twice times, fixed in 4% paraformaldehyde (PFA). The cover slip was removed from the 4-well plate and a glass slide was mounted on the cover slip and fixed. Images were obtained on confocal laser scanning microscope. For competition experiments, MCF7 cells were pre-incubated at 37 °C for 1 h in the presence of free biotin at the concentration of 1 mM.
**Supporting Figures**

**Figure S1.** Dependence of the fluorescence intensity of nile red (1 μM) on the concentration of SC4AH and SC4AB in water at 25 °C ($\lambda_{ex} = 540$ nm, $\lambda_{em} = 647$ nm).

**Figure S2.** Changes in turbidity of lipid vesicle solution (5 mM) upon increasing the concentration of (a) SC4AH from 0 to 40 mol% and (b) SC4AB from 0 to 20 mol% in water at 25 °C.

**Table S1.** Hydrodynamic diameter ($D_h$) of mixed liposomes (0.5 mM) with and without targeting and imaging agents, and after stored at room temperature for 6
months.
